## SI Methods

**Isolation of Actinomycete Test Species.** Actinomycetes were isolated on chitin-medium described by (1) and (2). Our basic protocol replicated the isolation protocol of these previous studies, with 2 exceptions. The 2 exceptions in our study were: (a) use of a saline buffer (rather than distilled water) to suspend bacteria when dislodging microbes from the ants through vortexing and (b) use of antibiotic-free medium for actinomycete isolation. Previous studies had supplemented isolation plates with antibiotics (nystatin and cycloheximide) to suppress growth of fungi during bacterial isolation, but we used antibiotic-free medium to permit simultaneous isolation of integument-inhabiting fungi (e.g., entomopathogens) that could be useful for testing of the antifungal properties of attine actinomycetes. Because all microbes grow very slowly on the minimum-carbon chitin medium, and because actinomycetes grew abundantly on culture plates, actinomycetes could be readily isolated from the chitin plates on the first attempt.

**Buffer for Suspension of Bacteria During Vortexing.** The saline buffer contained the same salt concentrations as the chitin-medium (0.7g K<sub>2</sub>HPO<sub>4</sub>, 0.5g MgSO<sub>4</sub>, 0.3g KH<sub>2</sub>PO<sub>4</sub>, 0.01g FeSO<sub>4</sub>, 0.001g ZnSO<sub>4</sub> dissolved in 1 liter ultrapure water).

**PCR Conditions and Sequencing.** Bacterial isolates were characterized by sequencing a segment of the 16S rDNA gene using the primer pair U519F and 1406R (3) (1  $\mu$ l 10x buffer, 0.8  $\mu$ l MgCl<sub>2</sub> 25 mM, 0.8  $\mu$ l dNTP mix [2.5 mM each nucleotide], 0.8  $\mu$ l 100x BSA, 0.6  $\mu$ l of each primer at 2 mM, 0.1  $\mu$ l Taq polymerase, 1  $\mu$ l template, and ddH<sub>2</sub>O to a total volume of 10  $\mu$ l). The PCR temperature profile was 94 °C for 1 min, 50 °C for 1 min, 72 °C for 2 min; repeat for 35 cycles; followed by a final extension step of 72 °C for 10 min. All PCR products were cycle-sequenced with the ABI Big Dye Terminator Kit (version 3.1) on an ABI PRISM 3100 automated sequencer.

**Bacterial Tag-Encoded Titanium Amplicon Pyrosequencing.** DNA was extracted from ants and gardens after dry ice methanol freezing and mortar and pestle grinding to a fine powder using methods detailed previously (4). Homogenized powder was resuspended in 500  $\mu$ l RLT buffer (QIAGEN) (with  $\beta$ -mercaptoethanol). A sterile 5 mm steel bead (QIAGEN) and 500  $\mu$ l 0.1 mm glass beads (Scientific Industries, Inc.) were added for complete bacterial lyses in a Qiagen TissueLyser (QIAGEN), run at 30 Hz for 5 min. Samples were centrifuged briefly, and 100  $\mu$ l 100% ethanol were added to a 100  $\mu$ l aliquot of the sample supernatant. This mixture was added to a DNA spin column, and DNA recovery protocols were followed as instructed in the QIAamp DNA Mini Kit (QIAGEN) starting at step 5 of the Tissue Protocol. DNA was eluted from the column with 30  $\mu$ l water and samples were diluted accordingly to a final concentration of 20 ng/ $\mu$ l for use with SYBR Green RT-PCR (Qiagen). DNA samples were quantified using a Nanodrop spectrophotometer (Nyxor Biotech). Bacterial tag-encoded titanium amplicon pyrosequencing and data processing were performed as described previously (5, 6). In short, raw data from bTEFAP was screened and trimmed based upon quality scores and binned into individual sample collections. Sequence collections were then depleted of chimeras using B2C2. The resulting files were then depleted of short reads (<200 bp) and bacterial species identified using BLASTn comparison to a curated high quality 16S database derived from National Center for Biotechnology In-

formation (NCBI). Data were compiled and relative percentages of a given bacterial species were determined for each sample. Data were also compiled at each individual taxonomic level according to the NCBI taxonomy criteria as described previously (5, 6). Collection and sequence information is deposited at GenBank under accessions SRA008625.9.

**Isolation of Ecologically-Relevant Test Fungi.** To accumulate a set of fungi (Table S4) for the testing of antifungal activities of the actinomycete isolates, attine cultivars and “weed” microfungi were isolated from attine gardens of the same nests from which actinomycetes had been obtained. Fungi were isolated from gardens about 6 weeks after the first actinomycete isolation (see SI Methods S5 for isolation procedure). Isolations were performed by carefully placing 8 garden fragments (2–4 mm diameter) with sterilized forceps on potato dextrose agar (PDA), using the methods of (7) for isolations of cultivars and using the methods of (8) for the isolation of noncultivar garden microfungi. Cultivars were obtained from all of the 7 nests, but noncultivar microfungi were obtained only from 5 of the 7 nests (Table S4). All microfungi obtained from attine gardens were used for testing except for 2 *Penicillium* isolates, which were excluded because of the great risk of contaminating the work environment with spores. One *Escovopsis* strain was isolated from the experimental nest of *C. wheeleri*. Two additional *Escovopsis* strains (one from *T. zeteki* from Panama, one from *T. turritex* from Texas) that had been obtained in previous *Escovopsis* surveys were added to the set of test-fungi. These 2 strains had been stored under glycerol at –80 °C since isolation in 2003 and 2006, respectively, but were revived 3 weeks before testing in 2008. Three filamentous fungi obtained from the chitin plates (see above; vortex of whole workers of *M. smithii*, *T. turritex*, and *C. wheeleri*) were also added to the set of test-fungi. One facultatively entomopathogenic fungus, *Fusarium solani*, was isolated from an *Atta texana* queen that had died in an incipient lab nest during spring 2008. One additional entomopathogenic fungus (*Acrodontium* sp.) was isolated from a diseased queen of *Acromyrmex versicolor* that had been collected from a mating flight in Arizona in 2007, then reared in a lab nest. Apart for the exclusion of the 2 *Penicillium* isolates mentioned above, the complete set of 14 noncultivar test fungi (Table S4) represents an unbiased selection of filamentous fungi available in the Mueller Lab shortly after isolation of the actinomycete species in 2008. Because these filamentous fungi were all isolated from attine gardens or from attine ants, the set of 14 test-fungi should be more representative for the problem fungi that ants encounter than standard laboratory species used traditionally for antibiotic testing. To increase the number of entomopathogenic test fungi, we added 5 *Beauveria* and one *Metarhizium* strains from the collection of Department of Agriculture–Agriculture Research Service (USDA-ARS) Plant Protection Research Unit, U.S. Plant, Soil and Nutrition Laboratory, Ithaca, NY 14853-2901.

Test-fungi were identified by sequencing of the ITS rDNA region using the universal primers ITS4 x ITS5 (9) and the LSU rDNA region using the universal primers LR5 x LROR (10). Sequences were compared via the BLASTn with information available at GenBank in September 2008. BLASTn results are listed in Table S4.

## SI Results

**Presence of Diverse Pseudonocardiaceous Bacteria in Single Attine Nests.** Tag-encoded 454-pyrosequencing yielded a total of 41,561 16S-sequences from 4 ant samples and 4 gardens (from *M.*

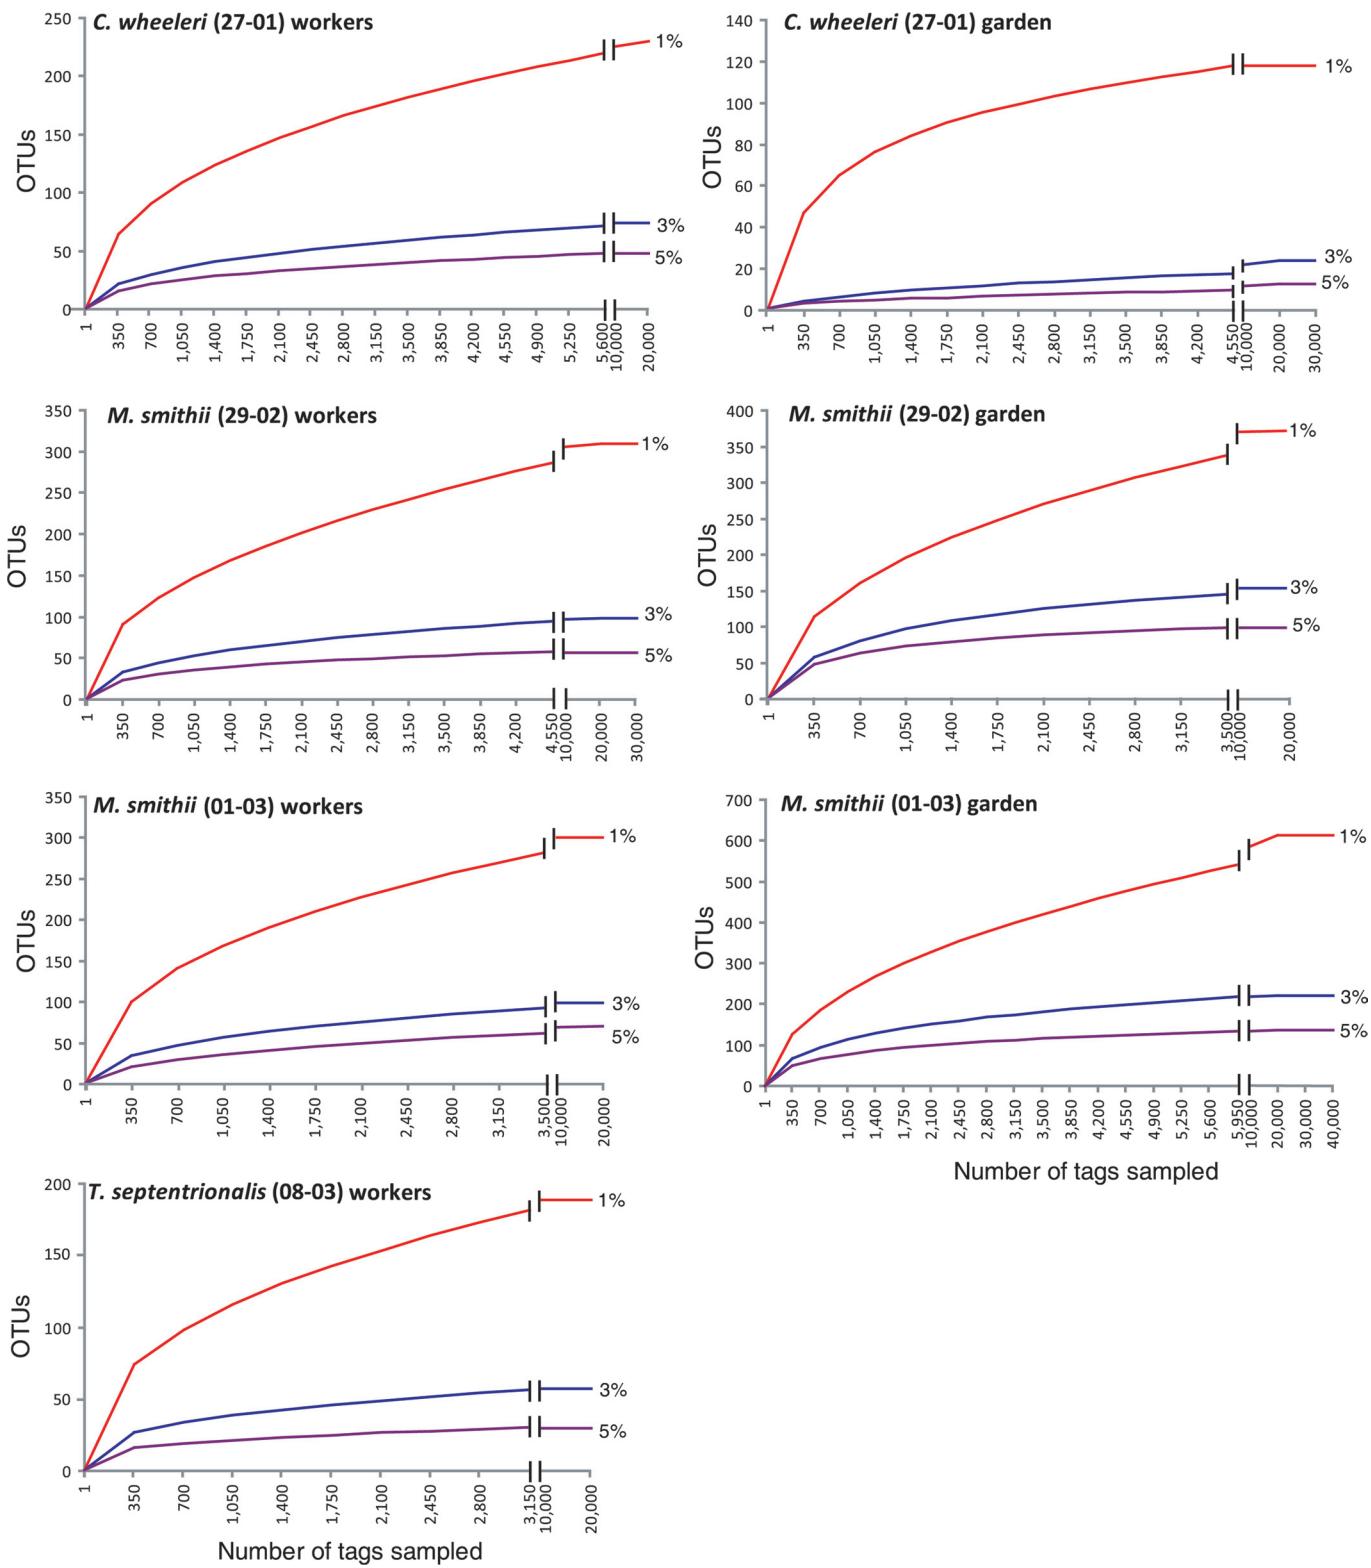

*smithii*, 2 nests; *C. wheeleri*, and *T. septentrionalis*) with an average sequence length of 457 bp. The garden sample of *T. septentrionalis* had to be discarded because it consistently yielded inadequate reads (fewer than 30 reads) in repeat 454-sequencing attempts. For the remaining samples, an average of about 5,400 16S-amplicons were characterized for worker-associated bacterial communities and an average of 6,600 amplicons for garden-associated bacterial communities. Rarefaction analyses indicate that this sampling regime of about 5,000 16S-amplicons per community appears sufficient to capture a significant proportion (if not most) of the bacterial diversities (Table S1, Figs. S1 and S2). Under the most stringent definition of Operational Taxonomic Units (OTUs; at least 1% sequence difference between OTUs), accumulation curves reveal 200–300 OTUs (observed) and 300–600 OTUs (predicted with additional sampling) for worker-associated bacterial communities, and 200–500 OTUs (observed) and 200–1000 OTUs (predicted) for garden-associated communities (Fig. S1, Table S1). Compared to other known bacterial communities (e.g., ref. 11), attine-associated bacterial communities emerge as moderately species-rich, even when using a stringent definition of OTUs (1% sequence difference). Additional diversity and richness indices [Shannon

diversity, Chao1 richness, ACE richness; Table S2] indicate that bacterial communities in the 2 gardens of *M. smithii* were moderately richer and more diverse (by about a factor of 2) than the corresponding communities on worker ants, whereas ant-associated bacterial communities were richer and more diverse than garden-associated communities in *C. wheeleri*. Because of the small number of samples screened, these diversity patterns should not be over-interpreted.

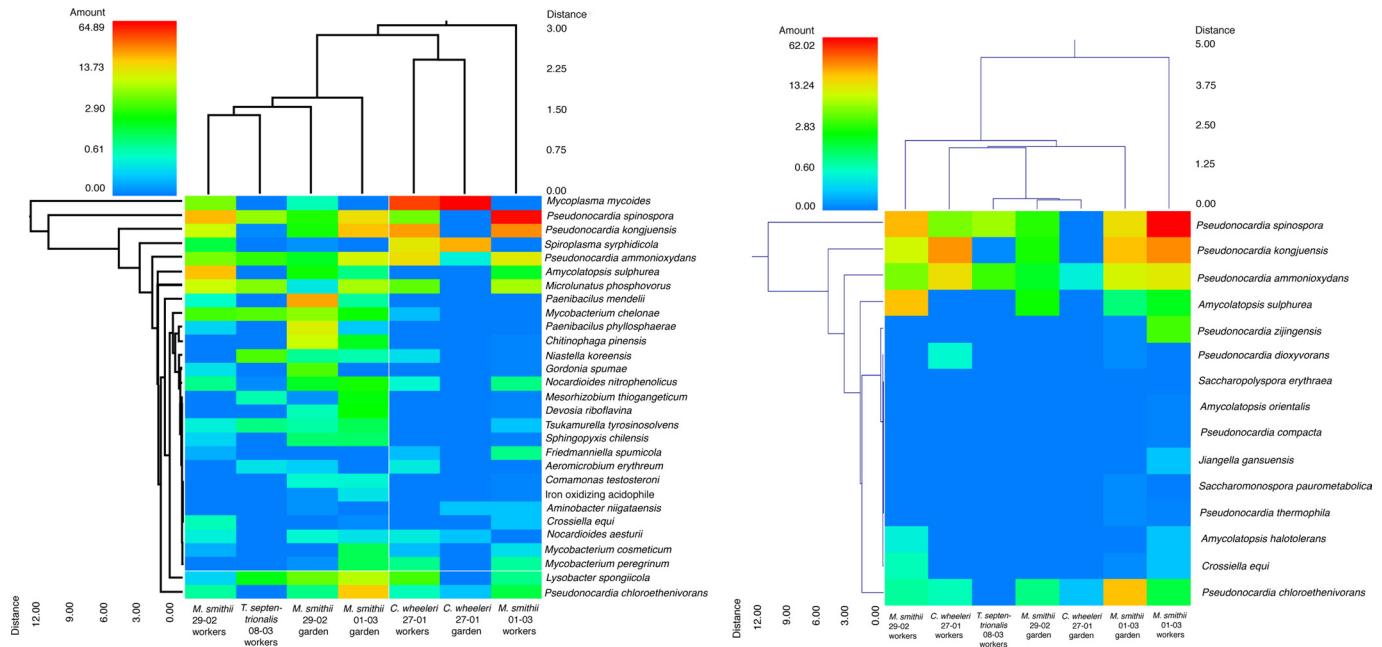

#### Amycolatopsis Identification in the Present Versus Previous Studies.

Previous culture-dependent studies had failed to identify *Amycolatopsis* from attine workers, for several reasons: First, *Amycolatopsis* was present only in *Mycocepurus smithii* samples, a species which had been screened only in one previous study (12). Second, because *Amycolatopsis* colonies exhibit mycelia-like fuzzy growth on the minimum-carbon isolation medium (unlike the button-like growth morphology typical for *Pseudonocardia*), previous researchers may have failed to recognize this growth form as an actinomycete. Third, fungicidal supplements in previous isolations could have precluded *Amycolatopsis* isolation on fungicidal medium but allowed such isolation on our antibiotic-free medium.

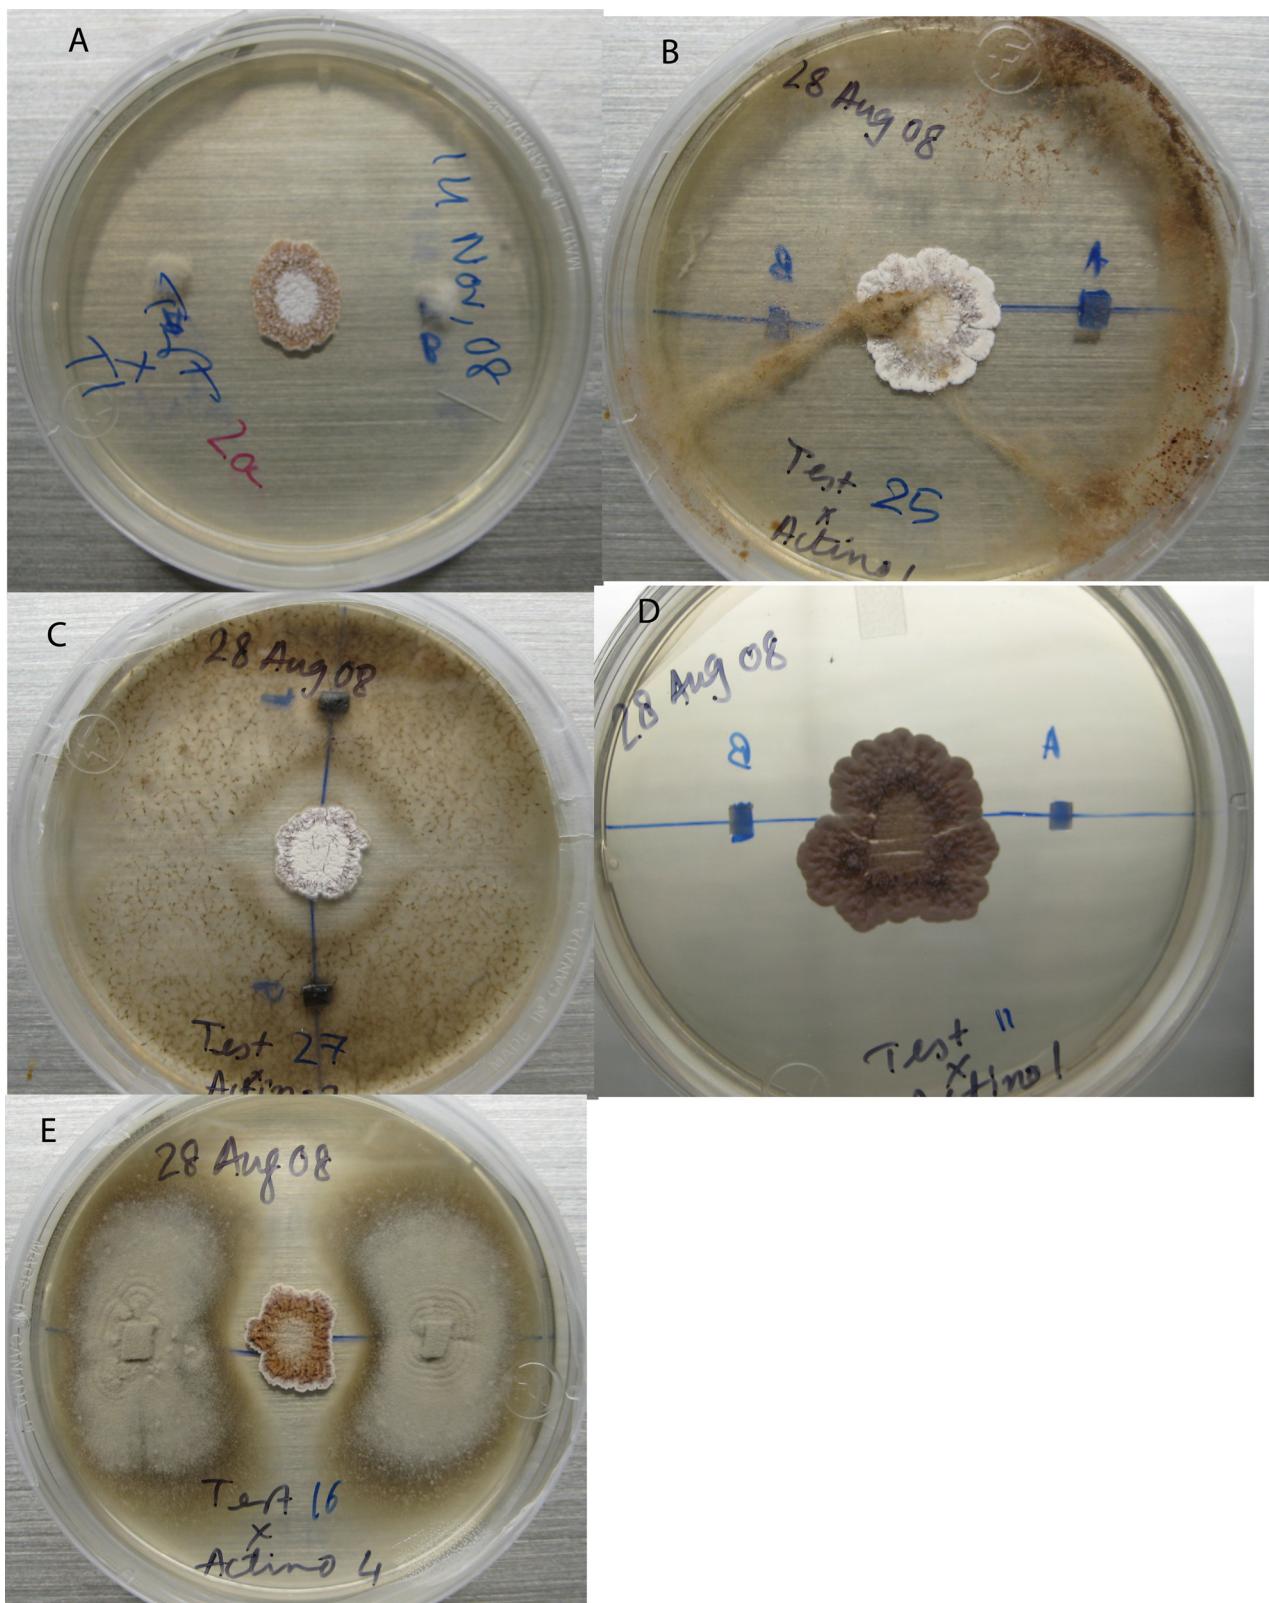

**Fig. S1.** Operational taxonomic unit (OTU)-accumulation curves and rarefaction predictions of OTU-diversity for each of the 7 bacterial communities screened. For each community, accumulation curves and rarefaction predictions are shown for 3 different stringency levels of defining OTUs (at least 1%, 3%, or 5% sequence difference between OTUs).

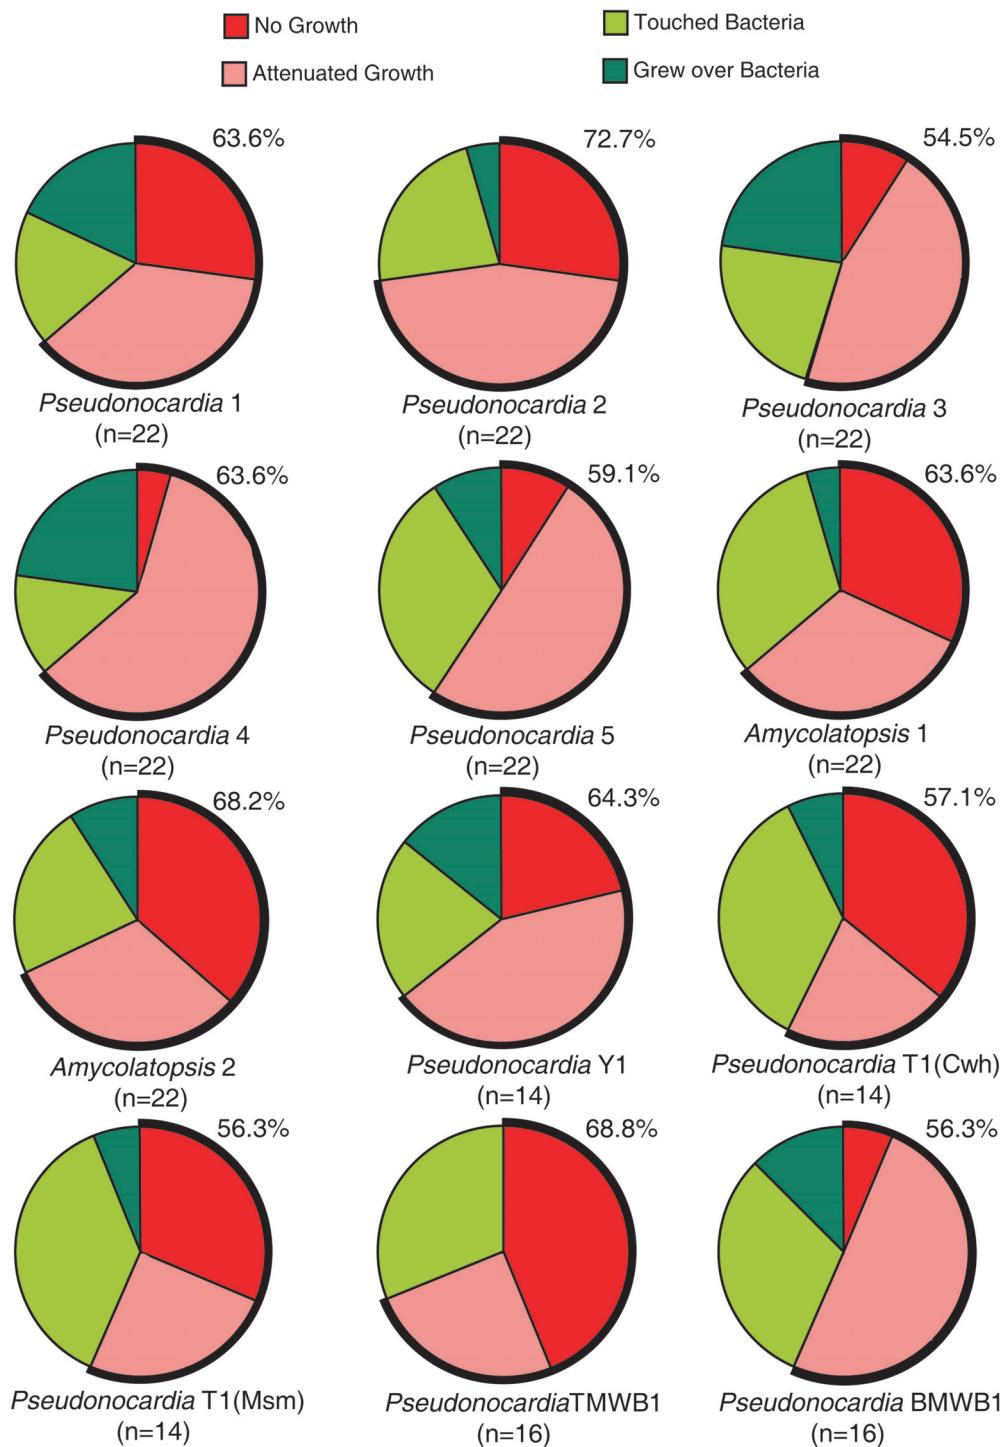

**Fig. S2.** Bacterial species identification and community composition obtained from 16S rRNA pyrosequencing of worker-associated and garden-associated bacteria species (*Left*) and pseudonocardiaceous species (*Right*) in 4 attine ant colonies. Bacteria from the same source are depicted in individual columns. The dendograms do not depict phylogenetic relationships; rather, dendograms cluster bacteria and communities by relative bacterial abundances. Contribution percentage of each bacteria is given in **Table S1**.

**Fig. S3.** Bacterial morphotypes growing on PDA agar at room temperature (see Table 2 for sources of isolation).

**Fig. S4.** (A-E). Assays testing antibiotic activity of *Pseudonocardia* (center of plate) against the same test fungus inoculated at 2 sides on the same plate. All photos were taken 28 days after inoculating the respective test fungus. (A) *Pseudonocardia*T1 vs. *Escovopsis*; (B) *Pseudonocardia*1 vs. *Escovopsis*; (C) *Pseudonocardia*2 vs. *Phoma*; (D) *Pseudonocardia*1 vs. cultivar; (E) *Pseudonocardia* vs. entomopathogen.

**Fig. S5.** Inhibition profile of *Pseudonocardia* and *Amycolatopsis* confronted with attine cultivars or different types of problem fungi. The extent of inhibition was scored as complete inhibition (no growth of test fungi), attenuated growth compared to control growth, and 2 types of no inhibition (fungi grew up to and touched the test bacterium but did not grow over the bacterium; test fungi grew over the test bacterium). The pie charts represent percentages of different growth responses by test fungi when challenged with a particular pseudonocardiaceous bacterium. Red sectors represent inhibited growth (total percentage given on the right side of each pie chart), green sectors unaffected growth; n is the number of fungi tested against each bacterium. (see Tables S3 and S4 for sources of isolation of bacteria and fungi, respectively). Authors will be able to provide raw data for each challenge upon request.

<sup>1</sup>*Acrodontium* is classified here as an attine pathogen because we have repeatedly isolated it from diseased *Acromyrmex* and *Trachymyrmex* queens kept in lab colonies.

<sup>2</sup>Crous et al. (1) discuss the close proximity of *Eucasphaeria* and *Niesslia*.

<sup>3</sup>*Verticillium leptobactrum* is classified here as a saprotroph because it is most frequently isolated from rotting plant material or soil, but less commonly from insect sources.
